Algebraic Approach to Recovering Topological Information in Distributed Camera Networks

Edgar J. Lobaton, Parvez Ahammad, Shankar Sastry

ABSTRACT

Camera networks are widely used for tasks such as surveillance, monitoring and tracking. In order to accomplish these tasks, knowledge of localization information such as camera locations and other geometric constraints about the environment (e.g., walls, rooms, and building layout) are typically considered to be essential. However, this information is not required for tasks such as estimating the topology of camera network coverage, or coordinate-free object tracking and navigation. In this paper, we propose a simplicial representation (called CN-Complex) that can be constructed from discrete local observations, and utilize this novel representation to recover topological information of the network coverage. We prove that our representation captures the correct topological information for coverage in 2.5D layouts, and demonstrate its utility in simulations as well as an experimental setup. Our proposed approach is particularly useful in the context of ad-hoc camera networks in indoor/outdoor urban environments with distributed but limited computational power and energy.

Camera Network Coverage, Distributed Sensing, Homology Theory, Topological Reconstruction

1. INTRODUCTION

Future generations of sensor networks are invariably going to include multiple types of sensors - including spatial sampling sensors such as cameras or active range scanners. Sensors like cameras will be the dominant consumers of bandwidth and power in such heterogeneous sensor networks. Thus, a clear understanding of the constraints (such as bandwidth consumption, power consumption, spatio-temporal sampling) posed by camera sensors in the context of computation and communication will play a critical role in defining the bounds for feasibility of performing certain tasks in a heterogeneous sensor network. In other words, such an understanding in the context of cameras could tell us whether our design of the heterogeneous network will be able to perform the designated task or not - and what conditions are necessary in order to perform such tasks.

Identification of the exact location of targets and objects in an environment is essential for many surveillance applications in the realm of sensor networks. However, there are situations in which the localization of the sensors is not known (e.g., unavailability of GPS, or ad-hoc network setup). A common approach to overcoming this challenge has been to determine the exact localization of the sensors and reconstruction of the surrounding environment. Nevertheless, we will provide evidence supporting the hypothesis that many of the tasks at hand may not require exact localization information.

Let us describe two potential scenarios in which some basic geometric information can aid in tracking and navigation for a large non-localized camera network:

1. Consider tracking of a target through an urban environment. In this scenario, it may be of interest to classify the path followed by the target. For example, it would be desirable for the network to specify whether the target went around a specific...
landmark instead of returning a list of cameras in which the target was visible. In this work, we propose to identify paths that are homotopic to each other (i.e. that can be deformed continuously from one to another). This allows distinguishing between paths that go around a building clockwise or counter-clockwise without worrying about specific cameras visited. Note that this cannot be done by knowledge of pairwise connectivity between cameras (as in the case of so called connectivity/vision graphs).

2. A second scenario where topological information is useful is navigation through an urban environment. This task can be accomplished by making use of local target tracking and a set of directions such as where to turn right, and when to keep going straight. In this case, a general description of our surroundings and the target location is sufficient to guide us around obstacles.

One of the fundamental questions in the context of camera networks is whether a network is limited to perform only tasks that a single camera can perform but at a larger scale, or if the total network is “greater” than the sum of the parts. Imagine a camera network where no inter-relationship between the cameras is known. It is natural to ask what the spatial relationship between cameras is. For surveillance application in which multiple views are certainly useful, we investigate how object tracking information from multiple cameras can be aggregated and analyzed. A related and important question here is as to how we manage the processing and flow of data between the cameras. We note that all of these questions can be approached using knowledge of the topology of the coverage of the network. In particular, topology awareness makes it possible to design more efficient routing and broadcasting schemes as it is discussed by M. Li et al [10]. This knowledge in turn can also aid the control mechanism for more energy-efficient usage.

In this paper, we consider a camera network where each camera node can perform local computations, and extract symbolic/discrete observations to be transmitted for further processing. This conversion to symbolic representation alleviates the communication overhead for a wireless network. This is a significant benefit as self-localization algorithms can be computationally expensive and require the exchange of large volumes of data. We then use these discrete observations to build a model of the environment without any prior localization information of objects or the cameras themselves. Once such non-metric reconstruction of the camera network is accomplished, this representation can be used for tasks such as coordinate-free navigation, target-tracking, and path identification.

The rest of the discussion is as follows: Section 2 gives a brief discussion about different approaches to capturing topological information in sensor networks and the related work in this domain; sections 3 and 4 contain our main theoretical contributions defining the problems and the assumptions made for topological recovery of the camera network coverage; simulations and actual experiment are discussed in sections 5 and 6. The contributions of this paper include the introduction of formalized topology recovery problems by making explicit assumption about the environment model, and the utilization of topological information for tracking and navigation.

2. RELATED WORK

Finding the topology of a domain embedded in $\mathbb{R}^2$ is closely related to detecting holes. There has been much work on the detection and recovery of holes by topological methods for sensor networks, most of which considers symmetric coverage (explicitly or implicitly) or high enough density of sensors in the field. In particular, Vin de Silva and Ghrist [5] obtain the Rips complex based on the communication graph of the network and compute homologies using this representation. These methods assume some symmetry in the coverage of each sensor node (such as circular coverage), however, such assumptions are not valid for camera networks. Spatial sampling of plenoptic function [2] from a network of cameras is rarely independent and identically distributed. The notion of spatial coherence encountered in the context

Figure 1: Physical layout (left) and simplicial representation (right) of an environment. In both cases we observe the paths of a target.
3. THE ENVIRONMENT MODEL

In this section the assumptions made for our problem are made explicit. Even though they may seem very restrictive, they are introduced in order to simplify the problem and facilitate the analysis.

3.1 The Problem in 2.5D

Our problem will be defined in terms of the detection of a target moving through an environment. For the sake of mathematical clarity, we first focus on the case of a single target moving through the environment. Let us start by describing our setup:

The Environment in 2.5D: We consider a domain in 3D with the following constraints:

- All objects and cameras in the environment will be within the space defined by the planes \( z = 0 \) (the “floor”) and \( z = h_{\text{max}} \) (the “ceiling”).
- Objects in the environment consist of static “walls” erected perpendicular to our plane from \( z = 0 \) to \( z = h_{\text{max}} \). The perpendicular projection of the objects to the plane \( z = 0 \) must have a piecewise linear boundary. Objects must enclose a non-zero volume.
- The Environment in 2.5D with the following constraints:

Cameras in 2.5D: A camera \( \alpha \) has the following properties:

- It is located at position \( o^{\text{3D}}_\alpha \) with an arbitrary 3D orientation and a local coordinate frame \( \Psi^{\text{3D}}_\alpha \).
- Its camera projection in 3D, \( \Pi^{\text{3D}}_\alpha : \mathcal{F}_\alpha \rightarrow \mathbb{R}^2 \), is given by
  \[
  \Pi^{\text{3D}}_\alpha (p) = (p_x/p_z, p_y/p_z),
  \]
  where \( p \) is given in coordinate frame \( \Psi^{\text{3D}}_\alpha \), and \( \mathcal{F}_\alpha \subset \{ (x, y, z) \mid z > 0 \} \), referred to as the field of view (FOV) of the camera, is an open convex set such that its closure is a convex cone based at \( o^{\text{3D}}_\alpha \). The image of this mapping, i.e. \( \Pi^{\text{3D}}_\alpha (\mathcal{F}_\alpha) \), will be called the image domain \( \Omega^{\text{3D}}_\alpha \).

The Target in 2.5D: A target will have the following properties:

- The target will be a line segment perpendicular to the bounding planes of our domain which connects the points \( (x, y, 0) \) to \( (x, y, h_\alpha) \), where \( x \) and \( y \) are arbitrary and \( h_\alpha \leq h_{\text{max}} \) is the height of the target. The target is free to move along the domain as long as it does not intersect any of the objects in the environment.
- A target is said to be detected by camera \( \alpha \) if there exists a point \( p := (x, y, z) \) in the target such that \( p \in \mathcal{F}_\alpha \) and \( o^{\text{3D}}_\alpha /p \) does not intersect any of the objects in the environment.

Note that these assumptions may seem very restrictive, but they are satisfied by most camera networks in indoor and outdoor environments. Also, some of these choices in our model (such as the vertical line target and polygonal objects) are made in order to simplify our analysis. We will see that our methods work in real-life scenarios through our experiments.

The example in figure 2 shows a target and a camera with its corresponding FOV.

PROBLEM 1. (2.5D Case): Given the camera and environment models in 2.5D, our goal is to obtain a representation that captures the topological structure of the detectable set for a camera network (i.e., the union of the sets in which a target is detectable by a camera). The construction of this representation should not rely on camera or object localization.
The formulation of the problem is very generic. We are choosing a simplicial representation because we are after a combinatorial representation that does not contain metric information. We are also after a distributed solution, i.e., processing information at local nodes.

### 3.2 Mapping from 2.5D to 2D

The structure of the detectable set for a camera network becomes clear through an identification of our 2.5D problem to a 2D problem. Since the target is constrained to move along the floor plane, it is possible to map our problem to a 2D problem. In particular:

- Cameras located at locations \((x, y, z)\) are mapped to location \((x, y)\) in the plane.
- Objects in our 2.5D domain are mapped to objects with piecewise linear boundaries in the plane.
- We can also do a simple identification between the FOV of a camera to a domain \(D_\alpha\) of a camera in 2D. A point \((x, y)\) in the plane is in \(D_\alpha\) if the target located at that point intersects the FOV \(\mathcal{F}_\alpha\). The set \(D_\alpha\) is the orthogonal projection (onto the \(xy\)-plane) of the intersection between \(\mathcal{F}_\alpha\) and the space between \(z \geq 0\) and \(z \leq \text{h}_{\text{target}}\). Since the latter is an intersection of convex sets, and orthogonal projections preserve convexity, then \(D_\alpha\) is convex. We can also check that \(D_\alpha\) will be open.
- Also, we can give a 2D description of the coverage of a camera. A point \((x, y)\) is in the coverage \(C_\alpha\) of camera \(\alpha\) if the target located at \((x, y)\) is detectable by the camera.

### 3.3 The Problem in 2D

We now proceed by characterizing our problem after mapping the original configuration from a 2.5D space to 2D. The following definitions are presented to formalize our discussion.

**The Environment:** The space under consideration is similar to the one depicted in figure 1 (left), where cameras are located in the plane, and only sets with piecewise-linear boundaries are allowed (including object and paths). We assume a finite number of objects in our environment.

**Cameras:** A camera object \(\alpha\) is specified by: its position \(o_\alpha\) in the plane; and an open convex domain \(D_\alpha\), referred to as the **camera domain**.

The camera domain \(D_\alpha\) can be interpreted as the set of points visible from camera \(\alpha\) when no objects occluding the field of view are present. The convexity of this set will be essential for some of the proofs. Some examples of camera domains are shown in figure 4.

**Definition 1.** The subset of the plane occupied by the \(i\)-th object, which is denoted by \(O_i\), is a connected closed subset of the plane with non-empty interior and piecewise linear boundary. The collection \(\{O_i\}_{i=1}^{N_\alpha}\), where \(N_\alpha < \infty\) is the number of objects in the environment, will be referred to as the **objects** in the environment.

**Definition 2.** Given a camera \(\alpha\), a point \(p \in \mathbb{R}^2\) is said to be **visible from camera** \(\alpha\) if \(p \in D_\alpha\) and \(\overline{o_\alpha p} \cap \left(\bigcup_{i=1}^{N_\alpha} O_i\right) = \emptyset\), where \(\overline{o_\alpha p}\) is the line between the camera location \(o_\alpha\) and \(p\). The set of visible points is called the **coverage** \(C_\alpha\) of camera \(\alpha\).

We consider the following problem:

**Problem 2.** (2D Case): Given the camera and environment models in 2D, our goal is to obtain a simplicial representation that captures the topological structure of the coverage of the camera network (i.e., the union of the coverage of the cameras). The construction of this representation should not rely on camera or object localization.

**Observation 1.** Note that the camera network coverage has the same homology (i.e., topological information) as the domain \((\mathbb{R}^2 - \bigcup O_i)\) if these two sets are homotopic (i.e., we can continuously deform one into the other).

### 4. THE \(\text{CN-COMPLEX}\)

Our goal is the construction of a simplicial complex that will capture the homology of the union of camera coverages \(\bigcup C_\alpha\). One possible approach for accomplishing this task is to obtain the nerve complex (see appendix A) using the set of camera coverage \(\{C_\alpha\}\). However, this approach will only work for simple configurations without objects in the domain. An example illustrating our claim is shown in figure 3.

The reason figure 3 (right) does not capture the topological structure of the union of camera coverage is because the hypothesis of the Čech Theorem (see appendix...
Before we proceed let us consider the following useful definitions:

**Definition 3.** Given the objects \( \{O_i\}_{i=1}^{N_o} \), a piecewise linear path \( \Gamma : [0, 1] \rightarrow \mathbb{R}^2 \) is said to be feasible if \( \Gamma([0, 1]) \cap (\bigcup O_i) = \emptyset \).

**Definition 4.** Given camera \( \alpha \) with camera domain \( D_\alpha \) and corresponding boundary \( \partial D_\alpha \), a line \( L_\alpha \) is a bisecting line for the camera if:

- \( L_\alpha \) goes through the camera location \( \alpha \).
- There exists a feasible path \( \Gamma : [0, 1] \rightarrow \mathbb{R}^2 \) such that for any \( \epsilon > 0 \) there exists a \( \delta \) such that \( 0 < \delta < \epsilon \), \( \Gamma(0.5 - \delta) \in C_\alpha \), \( \Gamma(0.5 + \delta) \notin C_\alpha \), \( \Gamma(0.5) \in L_\alpha \), and \( \Gamma(0.5) \notin \partial D_\alpha \).

If we imagine a target traveling through the path \( \Gamma \), we note that the last condition in the definition of a bisecting line identifies when an occlusion event is detected (i.e., the target transitions from visible to not visible, or vice versa). However, we will ignore the occlusion events due to the target leaving through the boundary of the camera domain \( D_\alpha \).

**Definition 5.** Let \( \{L_{\alpha,i}\}_{i=1}^{N_L} \) be a finite collection of bisecting lines for camera \( \alpha \). Consider the set of adjacent cones in the plane \( \{K_{\alpha,j}\}_{j=1}^{N_C} \) bounded by these lines, where \( N_C = 2 \cdot N_L \), then the decomposition of \( C_\alpha \) by lines \( \{L_{\alpha,i}\} \) is the collection of sets

\[
C_{\alpha,j} := K_{\alpha,j} \cap C_\alpha.
\]

Note that the decomposition of \( C_\alpha \) is not a partition since the sets \( C_{\alpha,j} \) are not necessarily disjoint.

The construction of the camera network complex (\( CN \)-complex) is based on the identification of bisecting lines for the coverage of each individual camera. This construct will capture the correct topological structure of the union of coverage of the network. Figure 5 displays examples of \( CN \)-complexes obtained after decomposing the coverage of each camera using their corresponding bisecting lines. The \( CN \)-complex captures the correct topological information, given that we satisfy the assumptions made for the model described in section 3. The following theorem (see appendix B for proof), states this fact.

**Theorem 1.** (Decomposition Theorem)

Let \( \{C_\alpha\}_{\alpha=1}^{N} \) be a collection of camera coverage where each \( C_\alpha \) is connected and \( N \) is the number of cameras in the domain. Let \( \{C_{\alpha,k}\}_{(\alpha,k) \in A_D} \) be the collection of decomposed sets by all possible bisecting lines, where \( A_D \) is the set of indices in the decomposition. Then, any finite intersection \( \bigcap_{(\alpha',k') \in A} C_{\alpha',k'} \), where \( A \) is a finite set of indices, is contractible.

Hence, the hypothesis of the Čech Theorem is satisfied if we have connected coverage which are decomposed by all of their bisecting lines. This implies that computing...
the homology of the $CN$-complex returns the appropriate topological information about the network coverage as a whole.

Observation 2. Note that there are many ways to decompose a set in order to obtain subsets with contractible intersections. However, by using the bisecting lines, we ensure that the decomposition can be done locally (at each camera node) without knowledge of the physical structure of the environment.

We note that the steps required to build the $CN$-complex are two-fold:

- Identify all bisecting lines and decompose each camera coverage.
- Determine which of the resulting sets intersect.

The first step makes sure that any intersection will be contractible. The second step allows us to find the simplices for our representation. These two steps can be completed in different ways which depend on the scenario under consideration. In sections 5 and 6 we illustrate the construction of the $CN$-complex for a very specific scenario.

4.2 From 2D to 2.5D

We can build the $CN$-complex by decomposing each camera coverage using its bisecting lines and determining which of the resulting sets intersect. However, a physical camera only has access to observations available in its image domain $\Omega^D$. Therefore, it is essential to determine how to find bisecting lines using information in the image domain.

We note that occlusion events occur when the target leaves the coverage $C_\alpha$ of camera $\alpha$ along the boundary of the camera domain $D_\alpha$ or along a bisecting line. We can verify that a target leaving through the boundary of $D_\alpha$ will be detected in the image domain $\Omega^D_\alpha$ as having the target disappearing/appearing through the boundary of $\Omega^D_\alpha$. If the target leaves $C_\alpha$ through one of the bisecting lines, we will observe an occlusion event in the interior of $\Omega^D_\alpha$.

Note that bisecting lines in the 2D problem corresponds to concurrent detections at corresponding cameras for the case of a single target in the environment. Finding overlap between these regions can be solved for the multiple-target case by using approaches such as the ones outlined in [12, 13, 20, 19, 4] in which correspondence and time correlation are exploited.

5. Simulations in 2D

We consider a scenario similar to the one shown in figure 1 (left) in which a wireless camera network is deployed and no localization information is available. Camera nodes will be assumed to have certain computational capabilities and they can communicate wirelessly with each other.

The assumptions for this particular simulation are:

The Environment in Simulation: The objects in the environment will have piecewise linear boundaries as described earlier. The location of the objects will be unknown. The location and orientation of the cameras is also unknown.

Cameras in Simulation: A camera $\alpha$ has the following properties:

- The domain $D_\alpha$ of a camera in 2D will be the interior of a convex cone with field of view $\theta_\alpha < 180^\circ$. We use this model for simplicity in our simulations.
- A local camera frame $\Psi^D_\alpha$ is chosen such that the range of the field of view is $[-\theta_\alpha/2, \theta_\alpha/2]$ when measured from the $y$-axis.
- Its camera projection $\Pi^D_\alpha : D_\alpha \to \mathbb{R}$, is given by

$$\Pi^D_\alpha(p) = px/\rho_y,$$

where $\rho$ is given in coordinate frame $\Psi^D_\alpha$. The image of this mapping, i.e. $\Pi^D_\alpha(D_\alpha)$, will be called the image domain $\Omega^D_\alpha$.

The Target in Simulation: A single point target is considered in order to focus on the construction of the complex without worrying about correspondence/identification of our target.

Throughout our simulations we will have the target moving continuously through the environment. At each time step the cameras compute their detections of the target and use their observations to detect bisecting lines. Observations at the regions obtained after decomposition using the bisecting lines are stored. These observations are then combined to determine intersections between the regions which become simplices in the $CN$-complex.
As mentioned before, the topology of the environment can be characterized in terms of its homology. In particular we will use betti numbers $\beta_0$ and $\beta_1$ (see appendix A). The $\beta_0$ number tells us the number of connected components in the coverage while $\beta_1$ gives the number of holes. The PLEX software package [1] is used for homology computations and corresponding betti numbers.

![Figure 6](image1.png)

**Figure 6:** A layout with two objects (left) where $C_3$ is shown. A circular hallway configuration (right) is shown. Dashed lines represent corresponding bisecting lines. Dotted curves represent the paths followed by the target.

**6. EXPERIMENTATION**

In order to demonstrate how the mathematical tools described in the previous sections can be applied to a real wireless sensor network, we setup an experiment tracking a robot in a simple maze. Figure 1 shows the layout to be used. We placed a sensor network consisting of CITRIC camera motes [6] at several locations in our maze and let a robot navigate through the environment. The $CN$-complex is constructed for this particular coverage and used for tracking in this representation. Homology computations are performed using the PLEX software package [1].

Time synchronization is required in order to determine overlaps between the different camera regions. The Flooding Time Synchronization Protocol (FTSP) [14] was used for this purpose.

At each camera node, background subtraction is performed at each frame. Once a target is detected, we perform further processing to detect bisecting lines (as shown in figure 7). However, note that the bisecting line processing occurs sparsely and hence power consumption is mostly due to background subtraction. Statistics on the power consumption for the CITRIC platform can be found in [6]. Note that the information extracted from each camera node is just a decomposition of the image domain with a list of times at which detections were made.

For our experiments the camera motes were capable of processing grayscale images at 4 frames per second at a resolution of $320 \times 240$ pixels. Symbolic information was then extracted and transmitted at a rate of 1 packet of 100 bytes every 10 seconds. We transmitted regularly even when there were no observations to transmit. If raw image data (without any compression) was to be streamed over the network, this would correspond to about $300 \, kBytes/s$ of data from a single mote. Instead, transmitting symbolic information in our experiment only accounts for $10 \, Bytes/s$.

![Figure 7](image2.png)

**Figure 7:** View of camera 5 from the layout in figure 1 before (left) and after (right) a bisecting line is found.

The complex is built by combining all local information from the camera motes. Each camera mote transmits the history of its detections wirelessly to a central computer that creates the $CN$-complex. The resulting complex contains the maximal simplices: $[1a \, 1b \, 1c \, 1d], [2a \, 2b \, 2c], [3a \, 3b \, 3c \, 3d \, 3e], [1a \, 1b \, 2c \, 3e], [1d \, 2a \, 3c], [2a \, 2b \, 3a], [1a \, 2b \, 2c \, 3a], [1a \, 2c \, 3a \, 3b], [1a \, 2c \, 3b \, 3c], [1a \, 2c \, 3c \, 3d], [1a \, 1b \, 1c \, 2e \, 3d \, 3e], [1c \, 1d \, 3e]$ and $[1d \, 2a \, 3e]$. The homology computations returned betti numbers: $\beta_0 = 1$ and $\beta_1 = 2$. This agrees with having a single connected component for the network coverage and two objects inside the coverage of the cameras.

In figure 6 (right) we observe similar results for a configuration that can be interpreted as a hallway in a building floor. There is a single bisecting line for all cameras. Our algebraic analysis returns $\beta_0 = 1$ and $\beta_1 = 1$. The latter identifies a single hole corresponding to the loop formed by the hallway structure. The list of maximal simplices recovered by our algorithm: $[3b \, 4a \, 4b], [2b \, 3a \, 3b], [1b \, 2a \, 2b], [1a \, 1b \, 4b]$.
simplices are visited by the robot’s path we can extract a path in the complex as shown by the dashed path in the complexes of figure 8. The main advantage of this representation is that the path in the complex gives a global view of the trajectory of the robot, while local information can be extracted from single camera views.

![Figure 8: Paths in the maze (shown in dashed lines): In the physical layout (left), and in the CN-complex (right). These paths can be compared by using the algebraic topological tools covered in appendix A.](image)

It is possible to identify paths in the simplicial representation that are homotopic (i.e., that can be continuously deformed into one another). The tools required for these computations are already available to us from appendix A. In particular, by taking two paths that start and end at the same locations forming a loop, we can verify that they are homotopic if they form the boundary of some combination of simplices. Equivalently, since a closed loop $\sigma$ is just a collection of edges in $C_1$, we need to check whether the loop $\sigma$ is in $B_1$ (i.e., in the range of $\partial_2$). This is just a simple algebraic computation. By putting the top and middle paths from figure 8 together we note that the resulting loop is not in the range of $\partial_2$ (i.e., they are not homotopic). On the other hand, the top and bottom paths can be easily checked to be homotopic.

7. SUMMARY AND DISCUSSION

In this paper, an algebraic representation of a camera network coverage is obtained through the use of discrete observations from each camera node. The mathematical tools used for this purpose are those of algebraic topology. In particular, we showed that given enough observations our model does capture the correct topological information.

The experiment using wireless camera motes illustrates how our representation can be used to track and compare paths in a wireless camera network without any metric information. For coordinate-free navigation, our representation can give an overall view of how to arrive at a specific location, and the transitions between simplices can be accomplished in the physical space by local visual feedback from single camera views. Using this proposed model allows for local processing at each node and minimal wireless communication. A list of times at which occlusion events were observed is all that needs to be transmitted. Also, all algebraic computations can be performed using integer operations as described in [9], which opens the doors to implementation on platforms with low-computational power. The homology computations in the experiment are done in a centralized fashion, however, distributed algorithms such as the ones introduced by A. Muhammad and A. Jadbabaie [15] can be used.

The approach described above can be extended to more complex environments with stairs, windows and building with multiple levels. In the future, we hope to extend this work to handle multiple targets and detection errors. In our experiments, simplices are drawn every time concurrent detections are observed. However, false detections can cause the discovery of incorrect simplices. This can be solved by constructing a non-deterministic complex that assigns probabilities to simplices. This will be the focus of our future research.

APPENDIX

A. MATHEMATICAL BACKGROUND

In this section we cover the concepts from algebraic topology that will be used throughout this paper. This section contains material adapted from [8, 5] and it is not intended as a formal introduction to the topic. For a proper introduction to the topic, the reader is encouraged to read [16, 9, 8].

A.1 Simplicial Homology

Definition 6. Given a collection of vertices $V$ we define a $k$-simplex as a set $[v_1, v_2, v_3, \ldots, v_{k+1}]$ where $v_i \in V$ and $v_i \neq v_j$ for all $i \neq j$. Also, if $A$ and $B$ are simplices and the vertices of $B$ form a subset of the vertices of $A$, then we say that $B$ is a face of $A$.

Definition 7. A finite collection of simplices in $\mathbb{R}^n$ is called a simplicial complex if whenever a simplex lies in the collection then so does each of its faces.

Definition 8. The nerve complex of a collection of sets $S = \{S_i\}_{i=1}^N$, for some $N > 0$, is the simplicial complex where vertex $v_i$ corresponds to the set $S_i$ and its $k$-simplices correspond to non-empty intersections of $k + 1$ distinct elements of $S$.

The following statements define some algebraic structures using these simplices.

Definition 9. Let $\{s_i\}_{i=1}^N$ (for some $N > 0$) be the $k$-simplices of a given complex. Then, the group of $k$-chains $C_k$ is the free abelian group generated by $\{s_i\}$. That is,

$$\sigma \in C_k \quad \text{iff} \quad \sigma = a_1 s_1 + a_2 s_2 + \cdots + a_N s_N$$

for some $a_i \in \mathbb{Z}$. If there are no $k$-simplices, then $C_k := 0$. Similarly, $C_{-1} := 0$.

Definition 10. Let the boundary operator $\partial_k$ applied to a $k$-simplex $s$, where $s = [v_1, v_2, \ldots, v_{k+1}]$, be defined by:

$$\partial_k s = \sum_{i=1}^{k+1} (-1)^{i+1} [v_1, v_2, \ldots, v_{i-1}, v_{i+1}, \ldots, v_k, v_{k+1}],$$

and extended to any $\sigma \in C_k$ by linearity.

A $k$-chain $\sigma \in C_k$ is called a cycle if $\partial_k \sigma = 0$. The set of $k$-cycles, denoted by $Z_k$, is the kernel $\ker \partial_k$ and forms a subgroup of $C_k$. That is, $Z_k := \ker \partial_k$.

A chain $\sigma \in C_k$ is called a boundary if there exists $\rho \in C_{k+1}$ such that $\partial_{k+1} \rho = \sigma$. The set of $k$-boundaries, denoted by $B_k$, is the image of $\partial_{k+1}$ and it is also a subgroup of $C_k$. That is, $B_k := \text{im} \partial_{k+1}$.

Even further, we can check that $\partial_k (\partial_{k+1} \sigma) = 0$ for any $\sigma \in C_{k+1}$, which implies that $B_k$ is a subgroup of $Z_k$.

Observe that the boundary operator $\partial_k$ maps a $k$-simplex to its $(k - 1)$-simplicial faces. Further, the set of edges that form a closed loop are exactly what we denote by the group of 1-cycles. We will be interested in finding out holes in our domains; that is, cycles that cannot be obtained from boundaries of simplices in a given complex. This observation motivates the definition of the homology groups.

Definition 11. The $k$-th homology group is the quotient group

$$H_k := Z_k / B_k.$$  

The homology of a complex is the collection of all homology groups. The rank of $H_k$, denoted the $k$-th betti number $\beta_k$, gives us a coarse measure of the number of holes. In particular, $\beta_0$ is the number of connected components and $\beta_1$ is the number of loops that enclose different “holes” in the complex.

A.2 Example

In figure 9 we observe a collection of triangular shaped sets labeled from 1 to 5. The nerve complex is obtained by labeling the 0-simplices (i.e., the vertices) in the same way as the sets. The 1-simplices (i.e., the edges in the pictorial representation) correspond to pairwise intersection between the regions. The 2-simplex correspond to the intersection between triangles 2, 4 and 5.

For the group of 0-chains $C_0$, we can identify the simplices $\{[1], [2], [3], [4], [5]\}$ with the column vectors $\{v_1, v_2, v_3, v_4, v_5\}$, where $v_i = [1, 0, 0, 0, 0]^T$ and so on.
Figure 9: A collection of sets (left) and corresponding nerve complex (right). The complex is formed by simplices: \([1,2],[2,3],[2,4],[2,5],[3,5],[4,5]\) and \([2,4,5]\).

For \(C_1\), we identify \([1,2],[2,3],[2,4],[2,5],[3,5],[4,5]\) with the column vectors \(e_1, e_2, e_3, e_4, e_5, e_6\), where we define \(e_1 = [1,0,0,0,0,0]^{T}\) and so on.

Similarly for \(C_2\), we identify \([2,4,5]\) with \(f_1 = 1\).

As we mentioned before, \(\partial_{k}\) is the operator that maps a simplex \(\sigma \in C_k\) to its boundary faces. For example, we have:

\[
\partial_{2}[2,4,5] = [4,5] - [2,5] + [2,4] \quad \text{iff} \quad \partial_{2}f_1 = e_6 - e_4 + e_3,
\]

\[
\partial_{1}[2,4] = [4] - [2] \quad \text{iff} \quad \partial_{1}e_3 = v_3 - v_2.
\]

That is, \(\partial_{k}\) can be expressed in matrix form as:

\[
\partial_{1} = \begin{bmatrix}
-1 & 0 & 0 & 0 & 0 & 0 \\
1 & -1 & -1 & 0 & 0 & 0 \\
0 & 1 & 0 & 0 & -1 & 0 \\
0 & 0 & 1 & 0 & 0 & -1 \\
0 & 0 & 0 & 1 & 1 & 1 \\
0 & 0 & 0 & 0 & 1 & 1 \\
\end{bmatrix}, \quad \partial_{2} = \begin{bmatrix}
0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 \\
-1 & -1 & 0 & 0 \\
1 & 0 & 0 & 0 \\
\end{bmatrix}.
\]

Since \(C_{-1} = 0\),

\[
H_0 = \mathbb{Z}_2/\mathcal{B}_0 = \ker \partial_{0}/\im \partial_{0} = C_0/\im \partial_{1}.
\]

We can verify that

\[
\beta_0 = \dim(H_0) = 1.
\]

Hence, we recover the fact that we have only one connected component in the diagram of figure 9. Similarly, we can verify that

\[
\beta_1 = \dim(H_1) = \dim(Z_1/\mathcal{B}_1) = \dim(\ker \partial_{1}/\im \partial_{2}) = 1,
\]

which tells us that the number of holes in our complex is 1. Also, \(H_2 = 0\) for \(k > 1\) (since \(C_k = 0\)).

\[\text{A.3 Cech Theorem}\]

Now we introduce the Cech Theorem which has been used in the context of sensor networks with unit-disk coverage and has been proved in [3]. Before we proceed further, we will require the following definition:

**Definition 12.** Given two spaces \(X\) and \(Y\), a homotopy between two continuous functions \(f_0 : X \rightarrow Y\) and \(f_1 : X \rightarrow Y\) is a continuous 1-parameter family of continuous functions \(f_t : X \rightarrow Y\) for \(t \in [0,1]\) connecting \(f_0\) to \(f_1\).

**Definition 13.** Two spaces \(X\) and \(Y\) are said to be of the same homotopy type if there exist functions \(f : X \rightarrow Y\) and \(g : Y \rightarrow X\) with \(g \circ f\) homotopic to the identity map on \(X\) and \(f \circ g\) homotopic to the identity map on \(Y\).

**Definition 14.** A set \(X\) is contractible if the identity map on \(X\) is homotopic to a constant map.

In other words, two functions are homotopic if we can continuously deform one into the other. Also, a space is contractible if we can continuously deform it to a single point. It is known that homologies are an invariant of homotopy type; that is, two spaces with the same homotopy type will have the same homology groups.

**Theorem 2.** (Cech Theorem) If the sets \(\{S_i\}_{i=1}^{N}\) (for some \(N > 0\)) and all nonempty finite intersections are contractible, then the union \(\bigcup_{i=1}^{N} S_i\) has the homotopy type of the nerve complex.

That is, given that the required conditions are satisfied, the topological structure of the union of the sets is captured by the nerve. We observe that in figure 9 all of the intersections are contractible. Therefore, we can conclude that the extracted nerve complex has the same homology as the space formed by the union of the triangular regions.

**B. PROOF OF THEOREM 1**

Throughout this section we consider a finite set of cameras indexed by \(\alpha \in \{1,2,3\ldots N\}\) with corresponding domains \(D_{\alpha}\) and coverages \(C_{\alpha}\). Each camera coverage is decomposed by all possible bisecting lines \(\{L_{\alpha,i}\}\). The collection \(\{C_{\alpha,j}\}\) is the result of this decomposition, where \(C_{\alpha,j} = C_{\alpha} \cap K_{\alpha,j}\) and \(K_{\alpha,j}\) is the convex cone resulting from decomposing the plane using the lines \(\{L_{\alpha,i}\}\) (see definition 11).

**Observation 3.** It may be useful for the reader to think of the set \(C_{\alpha}\) (the visible set after object occlusions have been removed) as the intersection of a convex set \(\{\mathcal{O}_i\}\) with a star convex set (due to visibility from \(\alpha_{o}\)).

**Observation 4.** The number of bisecting lines for a given camera in our environment is finite since we are considering finite number of objects in the coverage with piecewise linear boundaries.

**Definition 15.** The line segment joining points \(p\) and \(q\) is denoted by \(\overline{pq}\). The line passing through points \(p\) and \(q\) is denoted by \(L(p,q)\).

**Definition 16.** The triangle formed by points \(a, b\) and \(c \in \mathbb{R}^2\) is the convex hull of these three points and it is denoted \(\Delta_{a,b,c}\).

**Lemma 1.** Given that \(\alpha_{o}, p \in C_{\alpha}\) then \(\overline{\alpha_{o}p} \subset C_{\alpha}\).

**Proof.** Since \(\alpha_{o}\) and \(p \in C_{\alpha} \subset D_{\alpha}\), then \(\overline{\alpha_{o}p} \subset D_{\alpha}\) due to convexity of \(D_{\alpha}\). Let \(r \in \overline{\alpha_{o}p}\). If \(r\) is not visible then \(\overline{\alpha_{o}r} \cap \bigcup \mathcal{O}_i \neq \emptyset\) (where \(\mathcal{O}_i\) is the collection of objects in the environment). However, this implies that \(\overline{\alpha_{o}r} \cap \bigcup \mathcal{O}_i \neq \emptyset\). Hence, we conclude that \(p\) is not visible, which is a contradiction. Therefore, \(r\) must be visible. Since \(r\) was arbitrary then \(\overline{\alpha_{o}p}\) is visible.

**Lemma 2.** Given that \(p, q \in C_{\alpha}\) with \(L(p,\alpha_{o}) = L(q,\alpha_{o})\), then \(\overline{pq} \subset C_{\alpha}\). That is, if \(p\) and \(q\) are visible and are in the same line of sight, then the line joining them is visible too.

**Proof.** This follows from the definition of \(C_{\alpha}\) and the domain of a camera \(D_{\alpha}\). We know that \(D_{\alpha}\) is convex, so \(\overline{pq} \subset D_{\alpha}\), since \(p, q \in C_{\alpha} \subset D_{\alpha}\).

From our assumption \(L(p,\alpha_{o}) = L(q,\alpha_{o})\), it is possible to conclude that for \(r \in \overline{pq}\) then \(r \in D_{\alpha}\), and \(r \in \overline{\alpha_{o}p}\) or \(r \in \overline{\alpha_{o}q}\). Basically, there are only two cases, both \(p\) and \(q\) on the same side of \(\alpha_{o}\) or on opposite sides. Either way, \(r\) must be in \(\overline{\alpha_{o}p}\) or \(\overline{\alpha_{o}q}\).

Without loss of generality, assume \(r \in \overline{\alpha_{o}p}\). If \(r\) was not visible, the \(\overline{\alpha_{o}r} \cap \bigcup \mathcal{O}_i \neq \emptyset\) (where \(\mathcal{O}_i\) is the collection of sets representing the objects in the space). This implies that \(\overline{\alpha_{o}p} \cap \bigcup \mathcal{O}_i \neq \emptyset\), since \(\overline{\alpha_{o}r} \subset \overline{\alpha_{o}p}\). This implies that \(p \notin C_{\alpha}\), which is a contradiction. Therefore, \(r\) must be visible too.
Lemma 3. Given a closed path \( \Gamma^\alpha([0,1]) \subset \mathcal{C}_\alpha \), then the space enclosed by \( \Gamma \) is also in \( \mathcal{C}_\alpha \).

**Proof.** Let \( \mathcal{R} \) be the enclosed area by the path \( \Gamma \). Since \( \Gamma^\alpha([0,1]) \subset \mathcal{R} \) is bounded, then
\[
\exists M > 0 \text{ such that } ||\Gamma(t) - o_\alpha|| < M,
\]
where \( o_\alpha \) is the location of camera \( \alpha \). Hence,
\[
r \notin \mathcal{R} \text{ if } ||r - o_\alpha|| > M.
\]
Also, if a point \( r \) is connected to \( r \notin \mathcal{R} \) through a path \( \gamma \) that does not cross \( \Gamma \), then \( r \notin \mathcal{R} \).

Let \( p \in \mathcal{R} \) and define
\[
\mathcal{L} := L(p, o_\alpha) \cap \Gamma^\alpha([0,1])
\]
(i.e., points in \( \mathcal{R} \) and in the line passing through \( p \) and \( o_\alpha \)), then there must be points \( q_1, q_2 \in \mathcal{L} \) such that and \( p \in \mathcal{R} \). Otherwise, there would exist a point \( r \in \mathcal{L} \) such that \( ||r - o_\alpha|| > M \) (i.e., \( r \notin \mathcal{R} \)). This implies \( p \notin \mathcal{R} \) which is a contradiction. Therefore, \( p \notin \mathcal{R} \).

Next, we consider three cases:

\begin{itemize}
  \item Assume \( q_1 \neq o_\alpha \) and \( q_2 \neq o_\alpha \). Since \( q_1, q_2 \in \mathcal{L} \), then \( p \in \mathcal{R} \) by lemma 2 (which makes \( p \) visible).
  \item Assume \( q_1 \neq o_\alpha \) and \( q_2 = o_\alpha \). Then \( p \in \mathcal{R} \) by lemma 1.
  \item Assume \( q_1 = q_2 = o_\alpha \). Then, \( p, o_\alpha \in \mathcal{C}_\alpha \).
\end{itemize}

In all cases \( p \) is visible, and since \( p \) was arbitrary we conclude that \( \mathcal{R} \) is visible.

The previous lemmas are also true if we replace \( \mathcal{C}_\alpha \) by the set \( \mathcal{C}_{\alpha,j} \) resulting from a decomposition of the coverage. The reason why it works is because we can think of \( \mathcal{C}_{\alpha,j} \) as being the coverage of a camera with a domain
\[
\mathcal{D}_{\alpha,j} := \mathcal{D}_\alpha \cap \mathcal{K}_{\alpha,j},
\]
where \( \mathcal{K}_{\alpha,j} \) is the corresponding convex cone that generates the region \( \mathcal{C}_{\alpha,j} \). This new domain is still convex which is the property used in the previous lemmas. However, note that this \( \mathcal{D}_{\alpha,j} \) is not open.

Lemma 4. Every connected component of \( \bigcap_{(\alpha,j) \in \mathcal{A}} \mathcal{C}_{\alpha,j} \), where \( \mathcal{A} \) is a finite set of indices, is simply connected.

Proof. Let \( \Gamma \) be a closed loop in \( \bigcap_{(\alpha,j) \in \mathcal{A}} \mathcal{C}_{\alpha,j} \). By the previous lemma, the space enclosed by \( \Gamma \) is inside \( \mathcal{C}_{\alpha,j} \) for all \((\alpha,j) \in \mathcal{A} \).

Definition 17. Let \( \Gamma^\mathcal{A}([0,1]) = \mathbb{R}^2 \) be a path connecting points \( p \) to \( q \) (i.e., \( \Gamma(0) = p \) and \( \Gamma(1) = q \)). We define the region enclosed by \( \Gamma \), denoted by \( \mathcal{R}(\Gamma) \), to be the region enclosed by the set \( \Gamma^\mathcal{A}([0,1]) \cup \overline{\Gamma^\mathcal{A}} \).

Definition 18. A path \( \Gamma^\mathcal{A}([0,1]) = \mathbb{R}^2 \) connecting points \( p \) and \( q \) is said to be a convex path if \( \mathcal{R}(\Gamma) \) is convex.

Definition 19. A non-intersecting path \( \Gamma^\mathcal{A}([0,1]) = \mathbb{R}^2 \) is monotone with respect to camera \( \alpha \) if for any \( p \in \mathcal{S}_\alpha^1 \), where \( \mathcal{S}_\alpha^1 \) is the unit circle centered at \( o_\alpha \), we have that \( \Gamma^\alpha([0,1]) \cap L(p, o_\alpha) \) has a single connected component.

Lemma 5. Let \( \mathcal{R} \) be a bounded convex set contained between the lines \( L(p, o_\alpha) \) and \( L(q, o_\alpha) \), where \( p \) and \( q \in \mathcal{R} \). Then, either \( \mathcal{R} \) is the only path in \( \mathcal{R} \) joining \( p \), or there are (see figure 10(b) ) two distinct images of monotone paths connecting \( p \) to \( q \) only intersecting at the end points, which form the boundary of \( \mathcal{R} \).

The figure above illustrates the results from the previous lemma.

Lemma 6. Given that \( \mathcal{C}_\alpha \) is connected with \( p \) and \( q \in \mathcal{C}_\alpha \), then there exists a path \( \Gamma \) connecting these points that is convex and monotone with respect to camera \( \alpha \) with \( \Gamma^\alpha([0,1]) \subset \mathcal{C}_\alpha \cap \Delta_{p,q,o_\alpha} \).

Proof. We present an outline of the proof of this result.

Let \( p, q \in \mathcal{C}_\alpha \), where \( \mathcal{C}_\alpha \) is connected.

The reader may be tempted to try the path \( p \rightarrow o_\alpha \rightarrow o_\alpha \rightarrow q \).

However, we are not assuming \( o_\alpha \in \mathcal{C}_\alpha \). Our proof takes care of this case too.

Since \( \mathcal{C}_\alpha \) is connected then there exists a path \( \Gamma_\alpha \) that connects \( p \) to \( q \) with \( \Gamma_\alpha([0,1]) \subset \mathcal{C}_\alpha \). We illustrate this in the diagram in figure 10(a) in which the gray region corresponds to the coverage under consideration.

Our first objective will be to construct a path that is contained within \( \Delta_{p,q,o_\alpha} \).

We start with path \( \Gamma_\alpha \) and consider the line \( L(p, o_\alpha) \) (see figure 10(b) ). This line will intersect the \( \Gamma_\alpha \) at points \( \{r_1\} \).

By lemma 2 we know that the line segments between them are visible, so we can construct path \( \Gamma_1 \) as shown in figure 10(b) which does not cross \( L(p, o_\alpha) \).

Next, we consider the intersections between \( L(q, o_\alpha) \) and \( \Gamma_1 \) (see figure 10(c) ). Consider a segment of \( \Gamma_2 \) that is outside of the triangle \( \Delta_{p,q,o_\alpha} \), which intersects \( L(q, o_\alpha) \) at \( r_1 \) and \( r_2 \). For any \( r \in \Gamma_1 \cap \Gamma_2 \), we see that \( r \in \mathcal{D}_{p,q} \) since \( r_2 \in \mathcal{D}_{p,q} \). Also, there exists a path \( \Gamma_3 \) which is further away from \( o_\alpha \) than \( r_1 \) and \( r_2 \). Otherwise, the line segment in \( \Gamma \) between \( r_1 \) and \( r_2 \) would not be outside the \( \Delta_{p,q,o_\alpha} \). Therefore, \( r \) must be visible.

This implies that we can connect \( r_1 \) to \( r_2 \) by the line segment \( \Gamma_1 \cap \Gamma_2 \) and construct path \( \Gamma_3 \) which is inside \( \Delta_{p,q,o_\alpha} \).
In order to make $\Gamma_3$ into a convex path, we take the convex hull of $\Gamma_3$ and by lemma \ref{lem:convex-hull} we know that there are at most two monotone paths to choose from (see figure \ref{fig:convex-hull}). We choose the path $\Gamma$ that is closest to $\alpha$. Clearly $\Gamma$ is convex. We can see that $\Gamma$ is visible since for any line $L(r, o_\alpha)$ for $r \in \Gamma_3([0, 1])$, the line will have to intersect $\Gamma$ at some location $s$ closer to $o_\alpha$ than $r$.

This process yields the desired monotone and convex path $\Gamma$ (see figure \ref{fig:convex-hull}) which images is in $C_\alpha \cap \Delta_{p,o_\alpha,q}$.

**Lemma 7.** Given that $C_\alpha$ is connected with $p$ and $q \in C_{\alpha,j}$ for some $j$, there exists a path $\Gamma$ connecting these points that is convex and monotone with respect to $\alpha$ with $\Gamma([0, 1]) \subseteq C_{\alpha,j} \cap \Delta_{p,q,o_\alpha}$.

**Proof.** Since $p$ and $q \in C_{\alpha,j}$, then $p$ and $q \in C_\alpha \cap K_{\alpha,j}$. By the previous lemma, we know that there exists a path $\Gamma$ such that $\Gamma([0, 1]) \subseteq C_\alpha$. Note that $\Gamma([0, 1])$ is inside the cone formed by the lines $L(p, o_\alpha)$ and $L(q, o_\alpha)$ by construction.

This cone must be contained within $K_{\alpha,j}$, otherwise $p$ and $q$ could not be in $K_{\alpha,j}$. Therefore, $\Gamma([0, 1]) \subseteq K_{\alpha,j} \cap C_\alpha = C_{\alpha,j}$.

**Lemma 8.** Let $\Gamma : [0, 1] \rightarrow \mathbb{R}^2$ be a feasible monotone path connecting $p$ and $q \in C_\alpha$ with $\Gamma([0, 1]) \subseteq D_\alpha$, for some camera $\alpha$. If an object $O$ is within the region enclosed by $\overline{pq} \cup \Gamma([0, 1]) \cup \overline{qo_\alpha}$ then there exists a bisecting line $L$ passing through a point in $\Gamma$ that does not intersect $L(p_o, o_\alpha)$ and $L(q_o, o_\alpha)$ (not including these lines).

**Proof.** For simplicity we just give an outline of this proof. Since $\Gamma([0, 1]) \subseteq D_\alpha$, we know that no point in $\Gamma$ will be in the boundary of $D_\alpha$ since $D_\alpha$ is open.

Assume that the transition event occurs in $L(p_o, o_\alpha)$ or $L(q_o, o_\alpha)$ at some point $r \in \Gamma([0, 1])$ and nowhere else. Without loss of generality assume that $\overline{pq} \subseteq \Gamma([0, 1])$ (due to monotonicity of path). The object would have to occlude $r$ too (since objects are closed). Then either the path is not feasible or $p$ is not visible which contradicts our assumption. Therefore, a transition must occur at some other point along $\Gamma$ and not in these lines.

**Theorem 3.** (Decomposition Theorem) Let $\{C_\alpha\}_{\alpha=1}^N$ be a collection of camera coverages where each $C_\alpha$ is connected and $N$ is the number of cameras in the domain. Let $\{C_{\alpha,k}\}_{(\alpha,k) \in A_D}$ be the collection of decomposed sets by all possible bisecting lines, where $A_D$ is the set of indices in the decomposition. Then, any finite intersection $\bigcap_{(\alpha,k) \in A_D} C_{\alpha,k}$, where $A$ is a finite set of indices, is contractible.

**Proof.** For simplicity we just give an outline of this proof for two cameras. The proof for multiple cameras can be completed by induction. Let $p$ and $q \in C_{\alpha_1,k_1} \cap C_{\alpha_2,k_2}$ for some indices $(\alpha_1, k_1)$.

**Part I:**

First, consider cameras $\alpha_1$ and $\alpha_2$ on the same side of the line $L(p, q)$. We know that there exist convex monotone paths $\Gamma_i$, connecting $p$ to $q$ such that $\Gamma_i([0, 1]) \subseteq C_{\alpha_i,k_i} \cap \Delta_{p,o_\alpha,q}$ for $i = 1, 2$ (see left plot in figure \ref{fig:decomposition}).

By lemma \ref{lem:convex-hull}, we can choose a path $\Gamma$ corresponding to a segment of the boundary of $R := R(\Gamma_1) \cap R(\Gamma_2)$ (see right plot in figure \ref{fig:decomposition}). We choose the path that consists of segments from $\Gamma_1$ and $\Gamma_2$ so $\Gamma$ will be feasible. We note that lemma \ref{lem:convex-hull} also tells us that $\Gamma$ is monotone with respect to camera $\alpha_1$ (since $R$ is between $L(p, o_\alpha)$ and $L(q, o_\alpha)$).

Also, $\Gamma \subseteq R = R(\Gamma_1) \cap R(\Gamma_2) \subseteq D_{\alpha_1} \cap D_{\alpha_2}$ due to convexity of $D_{\alpha_1}$.

**Part II:**

Now we consider cameras $\alpha_1$ and $\alpha_2$ at opposite sides of the line $L(p, q)$. There are two main cases to consider.

**Case 1:**

For the first case we consider a configuration as seen in figure \ref{fig:decomposition} (left).

By lemma \ref{lem:convex-hull}, we know that there are no objects inside the regions enclosed by $\overline{qo_\alpha} \cup \Gamma([0, 1]) \cup \overline{qo_\alpha}$ (since otherwise there would be a bisecting line and we assumed that we already decomposed using all bisecting lines). Hence, $\overline{qo_\alpha}$ does not intersect any object for $s \in \Gamma([0, 1])$, which implies that $\Gamma$ is visible by both cameras (i.e. $\Gamma([0, 1]) \subseteq C_{\alpha_1,k_1} \cap C_{\alpha_2,k_2}$).

**Case 2:**

For the second case, we consider a configuration as shown to the left.

By following the same analysis as before, we can show that $\overline{pq} \cap \{r\}$ and $\overline{pq} \cap \{r\}$ must be visible by both cameras. However, we could have an object in $\alpha_1, \alpha_2$. Nevertheless, objects must enclose some area which does not allow an object to be contained in this line. Therefore, $\overline{pq} \subseteq C_{\alpha_1,k_1} \cap C_{\alpha_2,k_2}$.

**Figure 11:** Illustration of the construction of $\Gamma$.

**Figure 12:** Illustrations for Case 1.
